

Eclipse IDE Install

Course Document

Installing Eclipse, creating a project, and running Hello World

This assumes a Windows environment, but the process is similar for macOS and Linux. I have attempted to create a good starting point for the installation, but you may have to use your CIS skills to interpret and solve problems if something does not work as intended.

1. Install the JDK

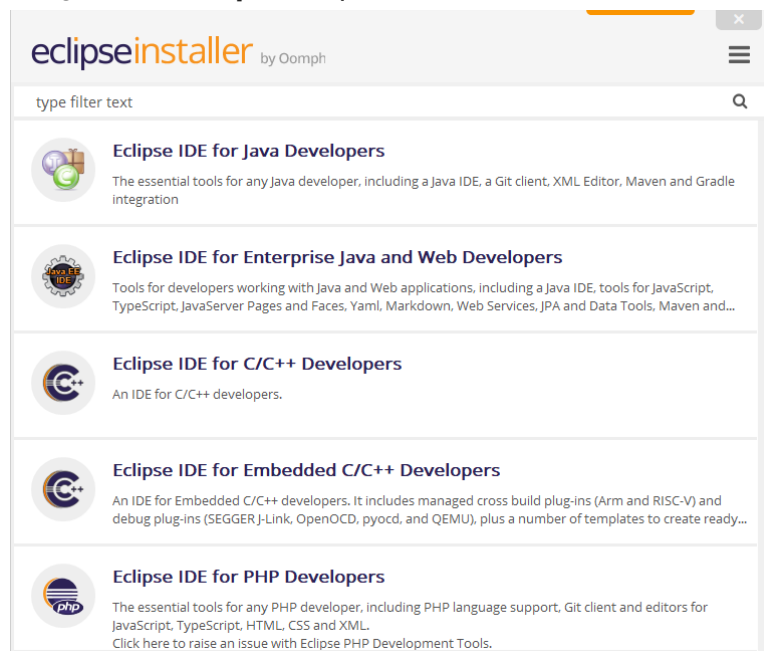

1. Download and install the Java JDK (25 or 26). All the default options should work.

Note: The screenshots in this guide show JDK 25 being installed and selected. If you use JDK 26 instead, your screens will show JavaSE-26 in place of JavaSE-25, but the steps are otherwise identical.

Alternative: The Eclipse IDE includes its own runtime environment, but installing the JDK first tends to work a little better. The rest of this guide assumes you installed the JDK first.

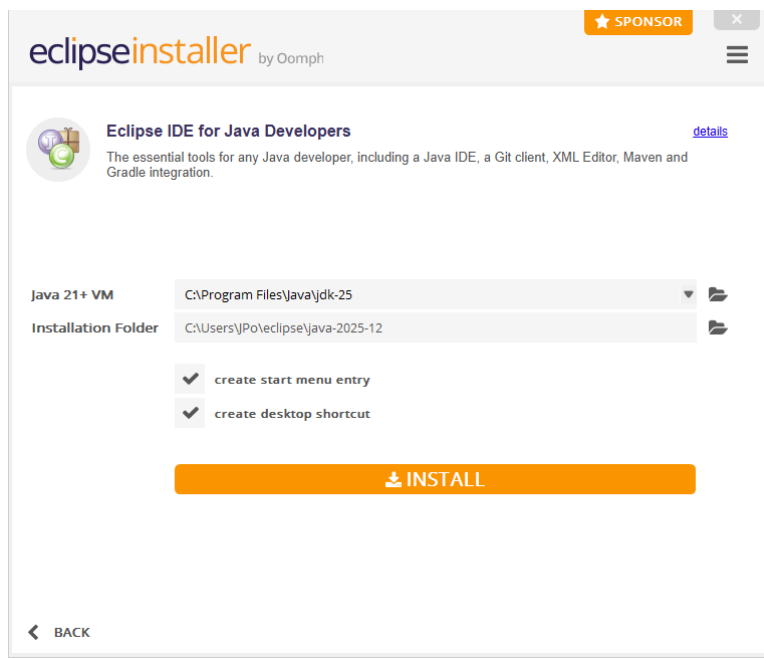

2. Install Eclipse

1. Download the latest version of Eclipse and run the installer.
2. Select the **"IDE for Java Developers"** option.

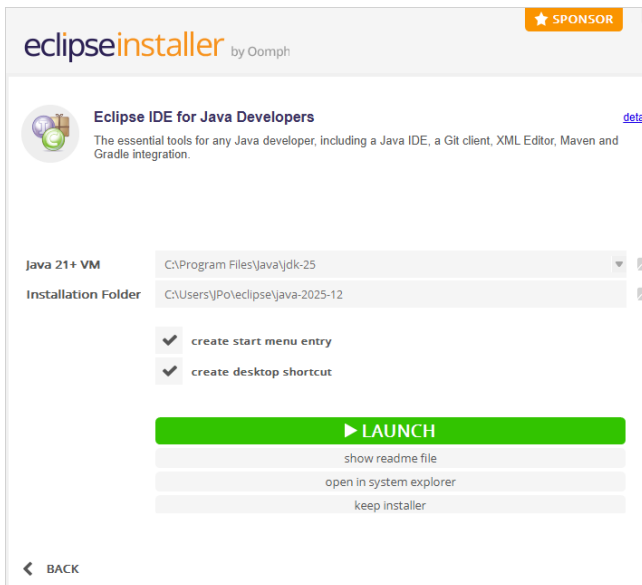

Selecting the IDE for Java Developers

3. Select the Java VM version. The dropdown should list the versions available; select the one you installed. You can set the installation folder, but the default should work.

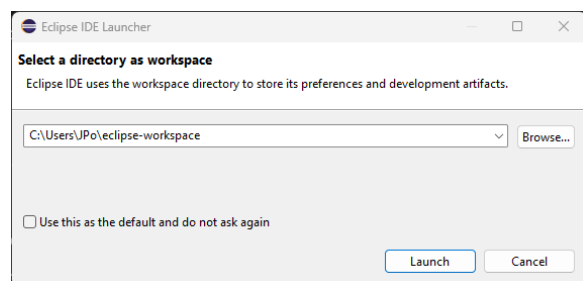

Selecting the installed Java VM

4. Read and accept the license. Depending on server and connection conditions, it may take a few minutes to download and finish installing.
5. Click **Launch** once installation finishes.

License and installation progress

Installation complete, ready to launch

3. Set Up Your Workspace

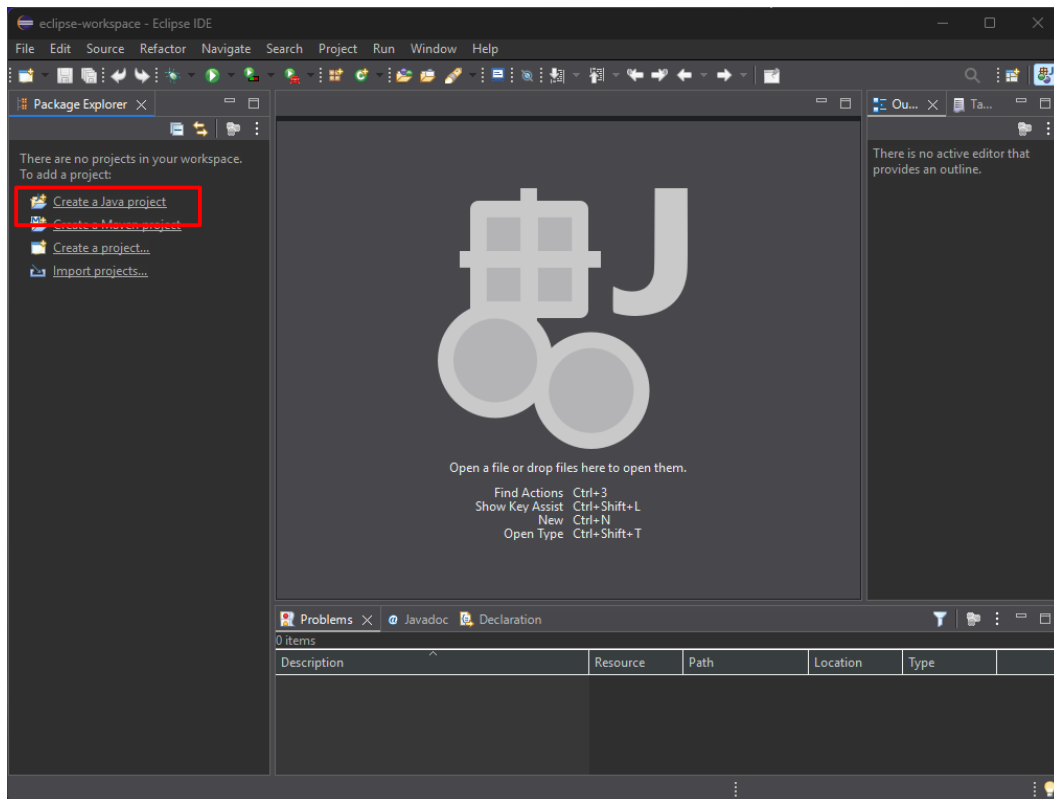

1. Create a workspace. The default Eclipse sets up for you is fine to start with.

Recommendation: I recommend a separate workspace for each course, plus one sandbox workspace for experimenting.

2. Exit the welcome screen. Take a few minutes to explore the menus and toolbars to familiarize yourself with the setup.

4. Create and Test a Java Project

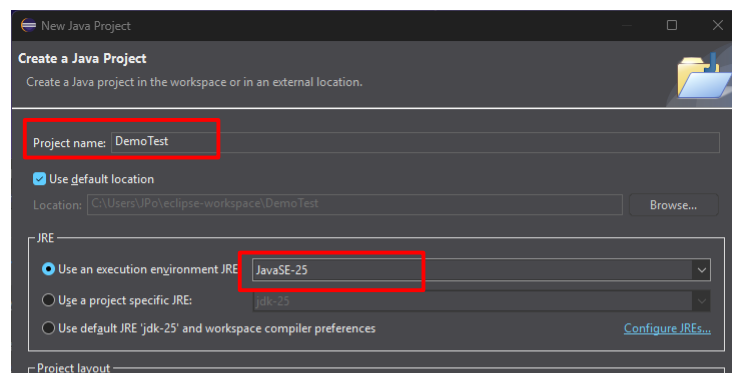

1. Create a new project. Use the option in the Package Explorer, or **File > New** in the menu.

Creating a new Java project

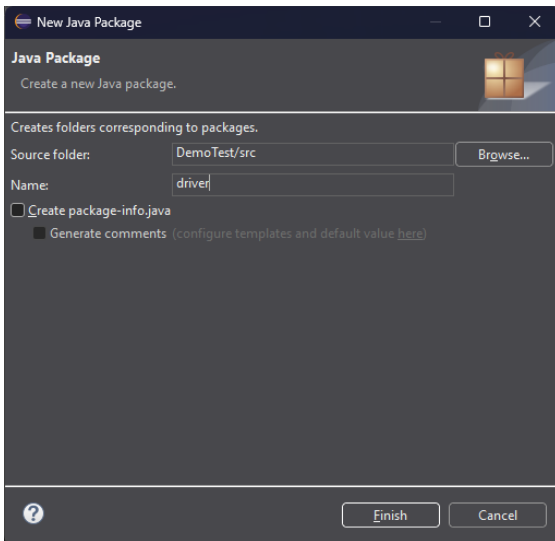

2. Give the project a name. The execution environment should automatically be recognized (JavaSE-25 in this example, but you can use 26).

Recommendation: Uncheck "Create module-info.java file."

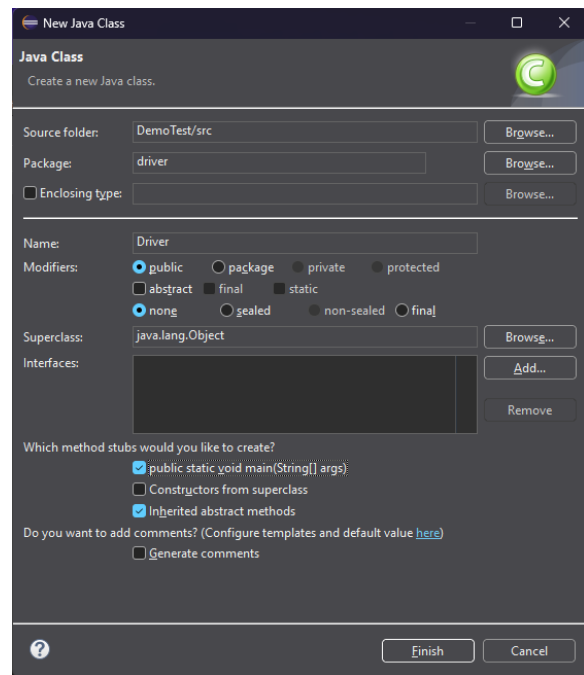

Naming the project

3. Click **Finish**. The Next option has some other settings, but the defaults work for this class.
4. Expand the project folder. Create a package in the src folder named driver (**File > New > Package**, or right-click src > **New > Package**). Click Finish.

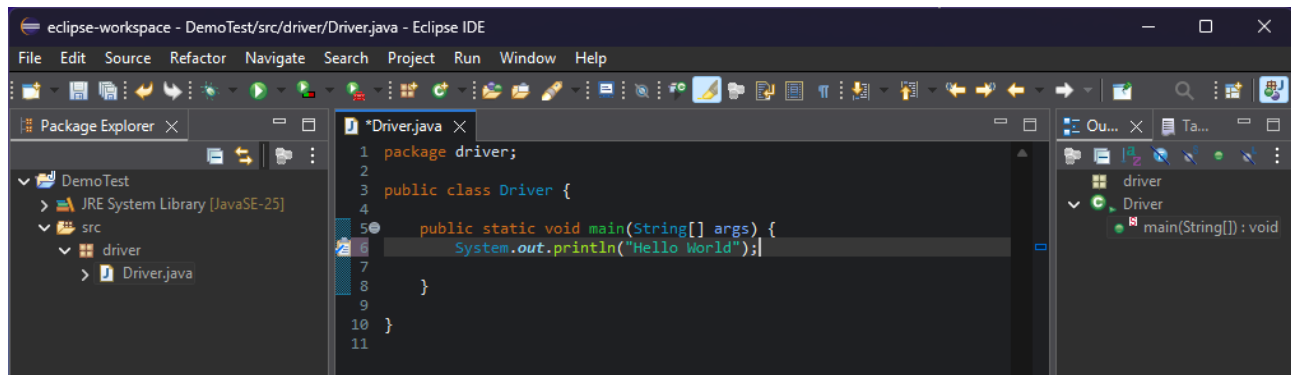

Creating a new package

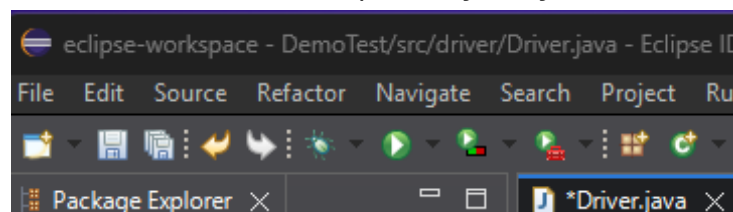

Naming the package driver

5. Create a new class in the driver package the same way. Name it Driver, and include the main method. Not all classes will have a main method.
6. Have the main method print "Hello World."

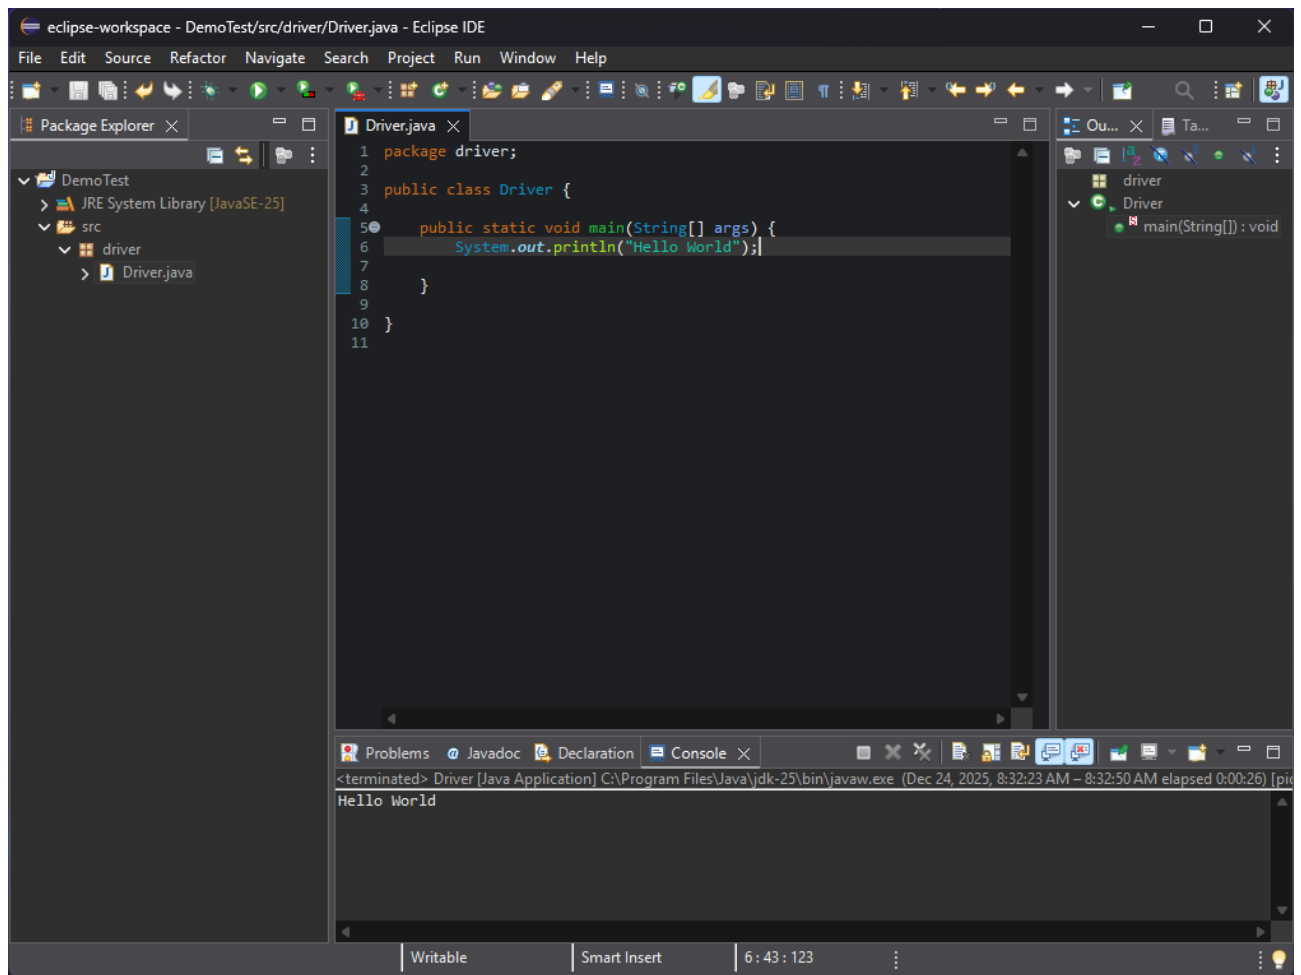

Printing Hello World from the main method

7. Click the compile and run button at the top. It may ask you to save the file first.

The compile and run button

8. Check the console for the output.

Hello World printed in the console
